FOUNDING WHITEPAPER / EXPERIMENT 01

When to fund a supplier payment

A read-only treasury experiment for Singapore importers paying US suppliers

Prepared for Aashmiin Kaur • 3 November 2026

The decision at 3 pm

It is Friday in Singapore. A controller can fund a USD 100,000 supplier payment now, or keep the SGD in the business until Monday. The supplier needs usable dollars on Wednesday. Before Friday's cutoff, can the controller show that Monday is actually an available option, that nobody else needs the same cash, and that waiting is worth the risk?

Our proposed capability is a timestamped funding decision record. For one legal entity, obligation and corridor, it shows the earliest binding constraint, the cash available after competing commitments, and the cost of two admissible funding choices. It explains why to keep the existing instruction when evidence is missing. A human uses the existing bank or provider to act.

Decision: test the information problem before building a platform. Financing an early supplier payment is a different business. A faster rail is useful only if transit drives the funding deadline. The interviews have not established which constraint dominates. This experiment is inexpensive enough to find out.

How to read the evidence

Verified means a supplied artefact, primary source or reproducible calculation supports the narrow claim. **Reported in interview** identifies testimony. **Assumption** covers the proposed design, all synthetic terms, prices and thresholds. **Unknown** marks an unresolved dependency. The payment narrative and financial tables are constructed examples; none describes an actual customer transaction. External reference links were checked on 3 November 2026.

For the founder: the experimental economics and stop conditions matter most. For treasury: inspect the assumptions about available cash and cutoffs. For engineering: the decision record and failure tests define the minimum product.

What the conversations actually establish

Reported in interview · supplied 2 November transcript, 14:49–18:35. An adviser describes a provider that asks an enterprise to deposit cash ahead of an FX payout. On some deals the provider advances money after assessing credit. The client keeps liquidity; the provider must find funding and absorb default exposure. The speaker explicitly qualified the timing and did not identify a representative sector. There is no transaction file, measured loss, enforceable bank term or buying commitment.

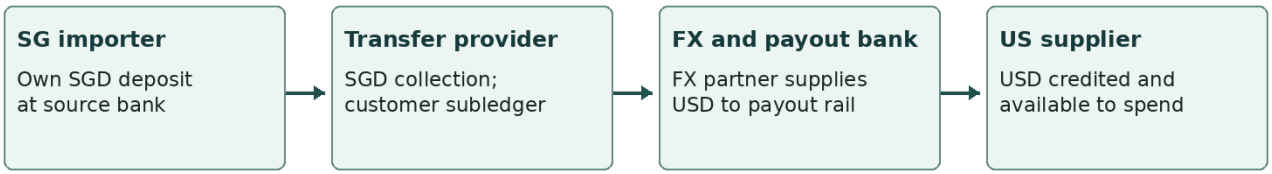

Independent framing. Three explanations would lead to different companies. The importer may have cash but fund unnecessarily early; the FX provider may need corridor inventory before dispatch; or the importer may lack cash until a customer pays. Only the first is principally a decision-support problem. Our accessible interview subject is the importer, not an assumed provider treasury customer.

Alternative lead	Decision and budget owner	What would beat the funding thesis
Receipt release · 04:29–05:09	Operations decides whether to release goods; finance validates an incoming payment.	Repeated orders are demonstrably held for missing attribution. A controlled decision changes dispatch time without false clearance.
FX and lot records · 20:46–21:26	Controller or accountant reconciles token units, currency value and subsequent disposal.	Material reconciling items survive existing tools and an accountant will supply records and fund a trial.
Funding time · 14:49–18:35	Treasury operator proposes timing; controller/CFO owns working capital and signs.	Permitted funding slack, continued delivery performance and demonstrably useful cash. If the buyer needs a loan, this fails.

Unknown: whether any lead is commercially stronger. Roughly 50 conversations were founder-reported across countries and roles, some after a demo (05:15–06:32; 09:09–12:19). They are not 50 independent demand confirmations. In the earlier 1 November transcript (16:26–19:01), an adviser wanted exceptions inside existing systems. That favours a bounded export or alert, not a second daily dashboard.

Following the money

Figure 1. Assumed incumbent route. The supplier accepts only USD in its US bank account. Arrows represent funds or settlement legs, never a status message. Ownership of a bank balance is a claim against that bank; title and safeguarding at an intermediary depend on the actual contract.

SGD deposit → provider collection. FX conversion → USD settlement. Final bank posting → usable USD.

When · all times SGT	Who owes whom and who can use the asset	Evidence, cutoff and risk
Thu 12 Nov · 09:00	Importer owes supplier USD 100k. Customer receivable is a separate claim; expected proceeds cannot fund an instruction.	Invoice, due date, cash ledger. Importer bears late customer risk.
Fri 13 · 15:00 early OR Mon 16 · 15:00 later	Importer transfers own SGD to provider via bank. Earmarked funds are unavailable to importer. Provider owes contractual performance, not an on-demand USD bank balance.	Bank debit + provider allocation. Fictional 16:00 cutoff. Match entity, amount and value date.
Before Wed 18 · 15:00	FX/liquidity partner delivers USD under its agreement. Provider reserves or funds payout bank capacity. Importer still owes supplier until contract discharge.	FX confirmation, inventory/limit and release condition; provider bears its own funding and partner risk.
Wed 18 · 15:00 → 23:00	Provider releases payout at 02:00 New York. Beneficiary bank controls final credit. Illustrative usable credit 22:30 SGT; deadline 23:00 SGT / 10:00 New York.	Dispatch ≠ credit. Obtain beneficiary available-balance evidence. Return/hold can defeat the anticipated availability.

The partner, bank and timestamps are fictional. No verified named provider promises these synthetic cutoffs. DBS distinguishes debit and indicative availability; Swift distinguishes arrival at the beneficiary bank and final credit. [O1] [O2]

The three clocks and their owners

Clock	Who pays for the gap	What moves the deadline
Receivable collection	Importer uses its cash or draws a committed facility while its own customer still owes it money.	Earlier collection, longer supplier terms or actual credit. Faster messaging does not create funds.
Corridor prefunding	Provider or FX partner holds local inventory; separately, the importer may post earmarked cash. Their balances are not additive savings.	A contractual change, approved credit or less inventory with the same service level. Identify who supplies replacement liquidity.
Settlement and payout	Provider releases, banks settle, supplier waits for usable USD. Someone still holds the intermediate exposure.	A different rail may reduce transit. FX conversion, off-ramp hours, limits, reviews and beneficiary credit can still bind.

Verified: the BIS describes opportunity costs from fragmented cross-border liquidity holdings in the banking system. It does not estimate what a Singapore importer would pay for a timing tool. [B1]

The control group

Before proposing a product, ask what the operator would have done with a shared calendar, AP export, confirmed balances and an existing bank facility. Reproduce the rule exactly: applicable holidays, maker/checker availability, funding lead, payout lead and an explicit safety buffer. Then test negotiating a later contractual date. A negotiated term that removes the whole problem is a success for the customer and a reason not to sell software.

Design decision. An early transfer is discretionary only when the buyer had an alternative under the terms and evidence available at the earlier choice. A later favourable quote cannot justify a Friday decision retrospectively. No deployment should advise waiting if the last safe baseline slot would expire before its alternative becomes evidenced.

Providers and the cheapest alternative

Verified · vendor documentation accessed 3 November 2026. These are comparison points for a Singapore payer and US bank beneficiary. Public estimates are not executable quotes, measured service levels or approved credit lines.

Alternative	What the provider publishes	What the buyer must verify
Airwallex	SG→US business route. Singapore pricing lists 0.4% above interbank on major FX, 0.6% otherwise; eligible local transfers free, SWIFT S$20–35. US docs describe next-day ACH for non-US clients and 1–2 business days.	Check currency tier, plan, cutoff, maximum and account-specific limit, weekend processing and net beneficiary amount.
Wise Business	Schedules and batch payments; Singapore business pricing describes volume discounts above S$30,000 qualifying monthly volume.	Obtain a timestamped business quote at USD100k. Retail-sized public calculator examples do not establish this fee.
Ripple Payments Direct	Documents prefunding, credit and just-in-time funding; in JIT, dispatch waits for funds.	SG→US access, precise route, underwriting, credit terms, fees and end-to-end SLA unknown.
DBS or existing bank	Import financing depends on bank terms and an offer/facility letter. An existing commitment may already solve the receivable gap.	Compare drawn interest, unused commitment fee, collateral, advance dates, repayment and eligibility.

Sources: Airwallex [M1] [M2] [M3]; Wise [M4] [M5]; Ripple [M8]; DBS [B2]. No commercial relationship or test account is claimed.

Assumption to attack: the calendar workaround cannot combine evolving cutoffs, encumbrances and reserved capacity reliably enough. Run its best version on exactly the same records. If it gives the same answers at lower cost, deliver the spreadsheet and stop. A prior competitor already checks exchange-origin receipts after receiving a transaction hash; the older AR idea also faces a credible incumbent. [B5]

One obligation under four funding arrangements

Assumption · not a provider quote. Every column pays USD 100,000 net into the same US bank account by the same Wednesday deadline. Reference SGD/USD is 1.35 SGD per USD; principal is SGD 135,000. Costs are additional, in SGD. The 30-day observation window contains one payment. Assume no other scenario differences unless shown.

SGD unless noted	Early	Later	Token rail	Credit
Customer capital restricted × calendar days	135,000 × 5	135,000 × 2	135,000 × 1	27,000 × 5
SGD-days of customer cash locked	675,000	270,000	135,000	135,000
Peak customer cash restricted	135,000	135,000	135,000	27,000
Average restricted customer cash over 30d	22,500	9,000	4,500	4,500
Interest or opportunity cost, 8%, Actual/365	147.95	59.18	29.59	29.59
FX execution spread (25 / 25 / 15 / 25 bp)	337.50	337.50	202.50	337.50
Rail or network fixed charge	20.00	20.00	3.00	20.00
Staff / route overhead	15.00	25.00	22.50	22.50
On-ramp 12 bp + off-ramp 20 bp	0	0	432.00	0
Facility fee 10 bp + draw interest 12% for 5d	0	0	0	356.92
Expected late loss (probability × event impact)	2.00	2.00	5.00	2.00
Expected unrecovered counterparty exposure	6.75	6.75	6.75	1.35
Expected residual token-price shortfall	0	0	3.38	0
All-in illustrative cost per paid invoice	529.20	450.43	704.71	769.86

Capital source by route. Cash-funded routes require the importer to provide the full principal (plus charges); peak and average above refer to earmarked principal only. Credit substitutes a partner balance sheet for 80% net exposure after collateral. A supplier that withholds goods or charges penalties after a late credit bears disruption even if it later collects in full.

The same-rail comparison isolates the timing decision; the token and credit columns are economic counterfactuals, not functioning integrations. Principal carrying cost ends at the common release checkpoint. The same later payout leg and beneficiary deadline still apply. Fee cash, interest after release and receipt use are not additional savings. Differential ordinary FX slippage is zero in the base case; add actual executable slippage separately if not already in quoted spreads.

Where the modeled benefit disappears

Verified arithmetic on assumptions. The customer’s own money is tied up for 5 or 2 days. Simple carry = 135,000 × annual differential rate × days / 365. Three days at 8% produce SGD 88.77. After SGD 10 extra processing, the conditional net advantage is SGD 78.77 before subscription. Restricted cash falls by 405,000 SGD-days; average restricted balance falls by SGD 13,500 across 30 days. Peak exposure on an individual transfer does not fall.

Cost of each gap. Early and later use the importer’s own bank balance; the 8% is hypothetical avoided borrowing or incremental return, not interest actually charged. The token route uses its own SGD for one day; liquidity partners supply ramp inventory and price FX and conversion into separate charges. A lender advances SGD 135,000 for five days with SGD 27,000 locked collateral. The borrower pays 12% draw interest plus a fee; nominal unsecured exposure is SGD 108,000. The model does not assume a lender will offer this facility.

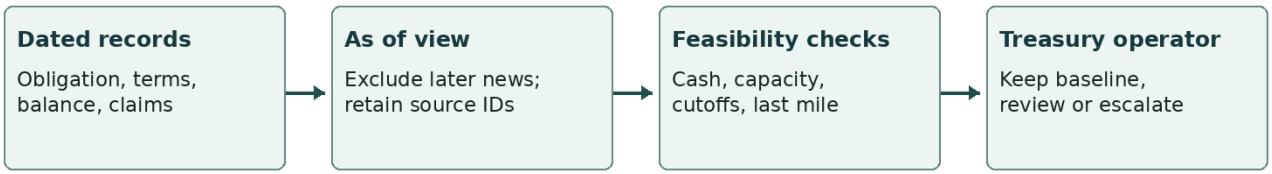

Underwriting is real work. Illustratively, funding SGD 135,000 at 8% for five days costs a lender SGD 147.95. Under an assumed per-draw default probability of 0.1% and 60% loss severity on the unsecured portion, its expected credit loss is SGD 64.80. The SGD 356.92 fee plus interest must cover both, capital, operations and the adverse tail. Do not charge lender loss again to the borrower. The borrower’s counterparty exposure line instead prices the risk to its posted cash.

Risk inputs, not measurements. Expected late cost: 0.2% × SGD 1,000; 0.5% on the token route. Expected counterparty loss: 0.01% × 50% of exposed cash. Residual token slippage/depeg beyond ordinary spreads: 0.25% × 1% of principal. Full quote incl. ordinary slippage, haircut, haircut changes and the cost of a fall-back rail remain unknown. Reject any comparison that quietly reduces the level of service.

The pivotal input is usable discretionary time at a real differential rate. Each avoidable day is worth SGD 29.59 at 8%; break-even on the SGD 10 increment is 0.338 day, or 0.90% annual differential over three days. Contractual buffer or idle cash at the same yield makes the incumbent SGD 10 cheaper. Just 5.84 bp worse FX, or 0.79 percentage points more late risk with a SGD 10,000 impact, erases the entire advantage. Equal deadlines alone do not establish equal reliability.

The decision mechanism

Figure 2. Data and decisions only. This system reads a dated export, builds a view of the world as known at a selected instant and produces a record. The user's existing treasury controls remain responsible for any instruction.

History is immutable in the experiment. Replays create new views; none writes to a bank or wallet.

Inputs. For one legal entity and currency pair: invoice and net beneficiary deadline; source balance snapshots; all other known reservations; forecast versus cleared receipts; FX rate, spread, fees and expiry; operating calendars; contractual cutoffs and maximum last-mile time; authenticated capacity or a documented fallback. Store event time and first-known time separately. A report generated on Monday cannot become Friday evidence because it describes a Friday event.

Decision rule. Compare candidate slots only if in the allowed contract/calendar, source cash net of other liabilities covers priced funding requirements, and destination capacity and remaining time cover the same deadline. Missing, stale or contradictory mandatory evidence yields unknown; a known constraint violation yields infeasible. The later option at Friday requires a credible forward commitment or a protected alternative, not hindsight. Without it the safe answer is to keep the incumbent option or ask for a binding offer.

Trust boundary. A bank snapshot proves a dated balance, not future cash; a provider acceptance proves submission, not beneficiary credit. A merchant operator can document an override, but may not turn an unsupported state into "verified". In a pilot use read-only scoped exports, no account numbers in shared demos, no signing credentials and separate consent for retention. Track "proposed → reviewed → manually acted → externally confirmed"; last two require external evidence and are not implemented by the replay.

What the prototype must get right

User and trigger	Action and required evidence	Acceptance test
AP analyst imports a week	Identify obligation and deadline from dated invoice; reconstruct balances from permitted records.	Replay at Friday; a Monday balance cannot change Friday output.
Treasurer reaches funding checkpoint	Compare candidate funding dates, spendable cash, competing reservations, FX/cost and both cutoffs.	Same cash cannot cover a concurrent payout twice. Missing or stale input withholds the comparison.
Treasurer reviews an exception	Keep baseline or seek provider confirmation. Show reason, amount short and record IDs.	Holiday, missed cutoff or failed payout route cannot appear ordinarily feasible.
Controller reviews economics	See restricted principal, capital-days, average, marginal cost and price sensitivity.	8% example reconciles to SGD 78.77 differential; at 0% the extra cost remains.
Reviewer reproduces decision	Use immutable fixture and explicit as-of time. Compare actual rules, calendar control and later slot.	Duplicate events do not alter output; conflicting evidence is blocked; no external writes.

Four incidents the happy path hides

Weekend or market closure: Friday cutoff passes; if Monday is closed the delayed slot is lost. Keep the original funding instruction when delay cannot be protected. **Receivable arrives late:** classify the forecast separately; reduce headroom only on committed outflows, increase usable funds only on settled evidence. If cash is short, obtain an existing committed facility through the bank or report the shortfall.

Off-ramp failure: a landed token does not meet the USD obligation. Without confirmed alternate capacity, mark deadline at risk; price emergency FX, network and late charges. **Concurrent payouts:** subtract the second instruction and compare again. If there is a shared liquidity pool, reserve atomically in any future live system; this single-obligation replay only tests supplied concurrent encumbrances.

Regulation and the system we will not build yet

Verified scope, not a licence opinion. Singapore's Payment Services Act and the MAS scope expansion cover specified payment activities; some facilitation can fall within the perimeter without possession of funds. Section 23 addresses safeguarding in defined circumstances. The licences and customer money arrangements of a bank or transfer partner do not automatically authorise a separate software firm. [O3] [O4]

Activity	Experiment boundary	Dependency for any expansion
Decision software	Local synthetic CSV in, read-only evidence out. No credential or instruction transmission.	Review exact data flows, service terms and disclosure with Singapore counsel.
Execution and FX	No booking, initiation, quote acceptance, conversion or routing.	Bank/PSP authority, customer permissions, operative agreement and documented cutoffs.
Custody	No wallets, keys, client pooled accounts or redemption.	Do not add unless separately authorised and funded; counterparties' balances are not ours.
Credit or broking	No lending, guarantees, referral commission or underwriting decision.	Underwriter, capital, loss allocation, collections and separate local legal review.

For permitted pilot files, minimise personal data, agree purpose and deletion date, separate organisations, restrict access, log exports and prove deletion. Determine whether cross-border processing or partner disclosure is permitted. Singapore's PDPC describes protection, retention and transfer limitation duties. [B3] No customer data has been processed in this experiment.

A database and signed imports can preserve provenance without a settlement network. A protocol becomes a research question only if independent providers will attest to cutoffs and capacity, buyers can verify the statements and no simpler API agreement works. A token does not supply working capital. None is required.

What we built and what we preserved

Verified in this study. A separate, local Python experiment reads a synthetic CSV, evaluates one USD obligation at two defined slots, emits JSON and renders a standalone HTML view. No bank connectivity, credential, paid API or money movement. The 22 automated tests passed through the shipped entry point and its underlying decision functions. This tests the mechanics, not predictiveness, demand, real cutoffs or payout reliability.

Run or open	Expected observation
friday.html	Monday is not yet observable. Keep the feasible baseline because binding future terms and fallback evidence are missing.
demo.html	Two independently feasible synthetic snapshots. SGD 78.77 retrospective difference. Friday's original decision remains unchanged; no beneficiary credit observed.
preagreed.html	Synthetic terms, slot, cash floor and fallback documented on Friday. Manual review of enforceability and cost; still no instruction to pay or unconditional saving.
delayed.html	Monday usable SGD 130,000; required SGD 135,382.50. Tuesday cash cannot fill Monday's SGD 5,382.50 shortfall. Comparison withheld.

Reproduce: unzip the supplied package; open friday.html in a browser. From its folder run python3 replay.py --html demo.html, then python3 -m unittest -v. The README lists cases for closed dates, competing payouts, unavailable off-ramp capacity, stale quote and a nine-hour last mile. Requires Python 3.9+ and time-zone data. No third-party packages.

What is worth reusing. After independently framing the funding decision we inspected the existing investigation-desk checkout and the prior Clearline papers. Reuse their exact-decimal, unknown-on-outage, versioned-evidence and approval patterns (src/lib/decimal.ts, chain/store.ts, platform/store.ts). The replay instead uses Python Decimal and CSV for portability. The prior checkout remains untouched; the new code lives in funding-replay/.

Assumption discarded: explaining an incoming transfer or allocating an invoice does not by itself identify when an importer may fund a different outbound obligation. A replay requires original decision-time balances, contractual permissions and supplier deadlines. FX lot valuation also requires its own accounting policy and benchmark; IAS 21 concerns foreign currency and does not by itself classify a stablecoin. [B4]

Who might buy and how the business could grow

Assumption. Sell a four-week read-only replay to a controller responsible for repeat supplier payments in one corridor. Offer SGD 500 flat, credited against an initial subscription if appropriate. Proposed recurring price: SGD 270 per legal entity per corridor per month, with agreed volume and support limits. Charge for a decision workflow, not a percentage of principal. The operator prepares the case; the controller owns the budget.

At the modeled SGD 78.77 differential, four suitable payments/month yield SGD 315.08 before the fee and only SGD 45.08 after it. Sixteen yield SGD 1,260.32 before the fee, but this is **not** a forecast: overlapping commitments, an unused cash balance, hedging costs, lower marginal rates or a costly reserved fallback can eliminate it. For a 2× buyer value/fee hurdle at SGD 270, require SGD 540 of documented gross monthly value net of incremental handling and risk; roughly seven genuinely comparable opportunities at the illustrative rate. Count separately evidenced labour savings once.

Bottom-up planning range [Assumption]. Suppose interviews ultimately identify 100–500 reachable entities with this currency pair; 10–30% have repeated actionable timing choices; 10–30% of those buy. At SGD 3,240 annual price, the arithmetic gives SGD 3,240–145,800 annual recurring revenue (1–45 buyers). The account counts and conversion rates are unmeasured scenario inputs, not a census or a market valuation. Replace them with named eligible firms, dated outreach, observed workflows and signed contracts. This corridor alone does not justify a venture-scale claim.

Unit economics. At SGD 270/month, an assumed SGD 15 data/hosting, 1.5 support hours at SGD 45 and SGD 30 monthly amortised onboarding cost leave SGD 157.50 contribution, about 58%, before sales, R&D, insurance and tax. At five support hours the same subscription contributes nothing. Price contracted integrations or decline them rather than disguise services revenue as software margin.

Expansion test. Require renewals at measured positive contribution, verified partner lead-time data, permitted reuse and independent evidence across three firms before a second corridor. A compounding asset might be a library of contractual cutoff exceptions with permitted, de-identified realised-versus-expected timings. Customers retain rights to their own records; providers must consent to reuse of their terms. A bank or TMS can neutralise this advantage with native schedules, richer outcomes or bundled funding. Pursue an API only when multiple partners request the same evidence contract.

Distribution and the two week decision

Verified public fit; unknown eligibility and interest. H.L. Yong distributes US brands [M9]; Food Spectrum describes US imports [M10]; Interocean Foods lists US meat imports [M11]. These are three prospects to qualify, not confirmed USD buyers or approved pilots. Product sourcing in the US does not prove that invoices are paid directly to a US bank account.

Prospect	Introduction route to request	Who must join
H.L. Yong	Ask an SMU accountancy alumnus in distribution for a controller introduction; otherwise request an AP referral via its public company channel.	AP operator plus finance signatory.
Food Spectrum	Ask an SMU/BIG food-business founder or adviser for an introduction; if no connection exists, use the published partnership channel.	Finance manager responsible for supplier funding.
Interocean Foods	Ask the PV adviser who offered network introductions to check for a trade/FX operator who can introduce a client with consent; use the firm's public contact if unavailable.	Treasury decision owner; separate provider-side witness if allowed.

Unknown: whether any intermediary knows these firms. No contact or permission is implied. Include one buyer with comfortable bank credit or no early-funding pain as a negative control. Airwallex's ZENXIN case describes pre-shipment payment and later retail receipts: useful evidence of different clocks, not a commitment or an independent savings estimate. [M14]

The fortnight

Days 1–3: seek six independent qualifying interviews, including one no-pain buyer. Reconstruct the last incident before demonstrating anything. **Days 4–7:** seek two authorised redacted weeks; one original provider term, bank snapshot and policy per firm. Catalogue all obligations including successes, misses and zero-action days. **Days 8–11:** replay the actual rule, calendar control and candidate rule at the same cutoffs. Have an operator independently adjudicate each case and document which fields arrived too late. **Days 12–14:** review findings with both signatories, freeze thresholds and offer a paid four-week shadow pilot with deletion and exit terms.

Interview script and falsification criteria

Begin: “Walk me through the last payout for which you had to move cash earlier than you wanted.” If there was none: “Walk me through your most recent overseas supplier payment, from approval until the supplier could use the money.” Do not propose a tool until that reconstruction is complete.

Ask: What currency, amount or range, due date and time zone? Which term set the earliest and latest funding dates? Who actually chose the date, and what did they know then? What restriction applied to the balance? Was there a receivable or credit line, and was it usable? What did staff do when late? Who paid interest, fees or penalties? Can we inspect a redacted instruction, dated term and evidence of supplier availability? What could a spreadsheet or renegotiated term already solve? Only then show the Friday screen and ask precisely which decision they would change.

Draft outreach for founder review. “I’m an SMU accountancy student studying how Singapore importers decide when to fund overseas supplier payments. Would you or the person who prepares your payment run walk me through one recent USD payout for 20 minutes? A case where your current process works well is equally useful. No account numbers or client names are needed.” No messages have been sent.

Proposed gate	Pass, pivot or stop
Behavioural pass	Within 14 days two unrelated treasury owners share an authorised redacted week, including original timestamps and cutoff evidence. Across the two, identify at least three discretionary decisions.
Commercial pass	One budget owner signs the SGD 500 four-week scope; agree a 2× monthly value/fee target, ongoing staffing cost, and no known additional deadline misses before expansion. Price, agreement and renewal are unproven.
Safety stop	Any false reassurance, cash-floor breach or deadline miss attributed to waiting pauses that rule. Track every abstention. Replay cannot prove noninferiority for rare failures; continue in prospective shadow mode.
Pivot	If credit or contract fixes timing on most cases, stop selling timing software. Test receipt release only with recent held orders; test FX records only with accountant-supplied lots and a paid review use case.
Evidence stop	If six qualified conversations yield no authority to change a date, or data access/paid interest fails after a completed scoped offer, stop development. If six interviews were not obtained, report recruitment failure rather than rejecting market demand.

Take this into the room

Say: "I'm testing whether your team can fund a supplier later without putting its payment deadline at risk."
Show: Friday's keep-baseline decision beside the cheaper Monday hindsight case.
Ask: "What could you actually have done with the cash, and did your agreement let you wait?"
Tomorrow: ask the adviser for a treasury introduction and book one walkthrough of an actual payout.
